I have tried replacing the two 12000uF PSU capacitors, as I found on Google that sometimes they can become depolarised but this has not solved the problem. I am trying to find a schematic for both the main board which has the PSU and the PA stage and the preamp board. Did you miss your activation email However, repairing it seems to be much harder than I thought as I supposed the switch to be broken, a missing connection, broken cable or something like that. First of all, does anyone have the schematic and could send it to me. I only have one of the DD2. By the way, the pedal was built in Japan, not in Taiwan dont know if this makes a difference anyway. Now heres whats wrong with the pedal When I step on it the LED turns on, but there is no effect at all. Like a permanent bypass. No parts that look like broken either. Does anybody have an idea what could be wrong with the pedal maybe someone had already similar problems with his DD3 and knows how to fix this. Could the main IC be broken are these ICs easy to destroy It would be nice if someone could help me, otherwise I guess I have to sell the pedal on EBay again. Thanks, Fat Mike I really need it. Thanks, Fat Mike Seems like this schematic is for both Effects. So why are there 2 different pedals Fat Mike If you hear audio at the second point, chances are very good that IC7 is fine and the fix will also be fairly easy. Let me know what you find and well take it from there. As long as IC7 is OK, you should be able to repair it. The first thing you should check is the correct supply at the end of this regulator. Then follow the signal path and see where the signal is lost. Seems like this schematic is for both Effects. So why are there 2 different pedals. Fat Mike The price of DRAM dropped hugely in 1986, so Boss reissued the DD2 as the DD3 and the DSD2 as the DSD3 rather than slashing prices on the existing pedals. There is now a newer version of the DD3 with a DD3A PCB, but I dont know when the change occurred. The first thing you should check is the correct supply at the end of this regulator. Then follow the signal path and see where the signal is lost.

There is nothing like the voice of experience. Do check the voltages first, then check for audio along the numbered test points in the schematic. I fixed an Ibanez Modulation Delay for somebody a couple months ago that had lost all of the effect. The problem turned out to be a bad 1uF cap that coupled two parts of the signal chain. Especially if you pick it up for a bargain in the first place and repair it for 10 cents. Especially if you pick it up for a bargain in the first place and repair it for 10

cents. Not today, babe. Im thinking of picking one up to mod, but SMD components would seriously discourage that. I havent had much time this week to check out any of your advices. And anyway, I dont even own a multimeteroops so I have to repair the pedal together with a friend actually I dont even know enough about electronics to repair this pedal on my owncry . But Ill probably have a look at the pedal again this weekend. However, none of the ICs is mounted on a socket. I could hear audio at both points, not quite clean, a little bit distorted, but it guess thats normalroll. I checked point 1, 3 and 5 as those were easily to find, could hear audio at all of them. So the microcontroller IC7 seems to be OK, right. So what else can I do now. I havent checked the 78L05 regulator yet as I didnt know howoops . Zero the hero, what exactly do you mean by Quote The first thing you should check is the correct supply at the end of this regulator Measuring the voltage at the output of that 78L05 regulator. If yes, which value is normal. Thanks again, Fat Mike. The DD 500 also includes a Tera Echo type, which is based on the TE 2 pedal released in. Produces endless repeats on demand in Hold mode.
